Measuring an agent

AI agents · University · Lesson 3

In this lesson you will

- Build a fixed test set with held-out wordings and names.
- Score exactly, and break the score down by group.
- Say honestly how sure a score is, and re-test after changes.

Key ideas

- A fixed test set, answers decided first, scored the same way.
- Trained wordings measure memory; held-out ones measure skill: 16/16 against 13/16.
- 29 out of 32 is roughly 76% to 97%: small sets find failures, big ones pin numbers.

Activity: Write the agent's exam

1. Write (6 min): Ten requests for a made-up timetable agent.
2. Answer key (4 min): The right call for each, before testing.
3. Swap and run (6 min): A partner plays the agent.
4. Score (4 min): Exact match, by group. What failed?

Use made-up classes and days only. A fixed list of phrases for the "agent" makes the unusual wordings fail, just as a small model does.

Let’s discuss

1. Why must the answers be written before the agent runs?
2. What would you need to trust a score enough to deploy an agent?
3. Which of your study tools has never been tested on your own language?

Exit ticket

- One thing a fair test set must contain, and why 29 out of 32 is not exactly 91%.
