Several agents, one job

AI agents · University · Lesson 2

In this lesson you will

- Split an agent into planner, checker, runner and person.
- Write strict rules that stop a bad call before it runs.
- Weigh what more roles cost: tokens and compounding errors.

Key ideas

- One part proposes; another checks before anything runs.
- Strict rules in code make the first checker: they never guess.
- Errors multiply: two steps at 90% are both right only 81% of the time.

Activity: Planner and checker

1. Set-up (3 min): Groups of three: planner, checker, runner.
2. Play (10 min): The planner writes calls; the checker applies five rules.
3. Swap (5 min): Change roles and try to sneak a slip past.
4. Debrief (2 min): Which slip got through, and why?

Write the five rules large enough for the checker to read at a glance. Use only made-up names and classes.

Let’s discuss

1. Which mistakes can strict rules never catch?
2. When is a second model worth its cost as a checker?
3. Why should a stopped call go back to a person instead of a silent retry?

Exit ticket

- Write one checker rule as Python or pseudocode, and one slip it would stop.
