Lesson plan · for the teacher

Map your school's AI risks

AI security · Level 4 · Lesson 1

Time
55 min

Materials
A large sheet of paper or the board; A list of the AI tools staff and pupils use (ask around first); Sticky notes or slips of paper, one per tool

Learning goals

- List the AI tools in use, with their data and their powers.
- Find the paths for untrusted text, and score each risk.
- Give the top risks a control and an owner.

Activity: A risk map in an hour

1. Warm-up (5 min): Ask everyone to write down how many AI tools they think the school uses. Collect the guesses: most people guess one or two.
2. Inventory (15 min): Put one sticky note per tool on the sheet, from free chatbots to the parents' bot. For each, write what data it touches, what it can do (read or act), who uses it and who looks after it.
3. Paths in (10 min): Mark with a red dot every place the tool reads text nobody at school wrote: web pages, essays, parents' messages, tool results.
4. Score (15 min): Score each risk for likelihood and impact from 1 to 3 and multiply. Circle the top three, and give tools that act an extra look.
5. Owners (10 min): For each circled risk, agree a control that changes the system, a named owner and a review date. Write them on the sheet.

Ask around before the session: staff and pupils often use tools nobody has listed. Keep the names of pupils and staff off the sheet. If the school has a cyber risk register, bring it and add the AI rows.

Discussion

- Which tool surprised you by being on the list?
- Why do tools that act need the hardest look?
- What makes a control stronger than a piece of advice?

Exit ticket

- Write your school's top AI risk, its score, and who will own it.

Try it at school tomorrow
With two colleagues or your pupils' AI club, list every AI tool the school uses, mark where untrusted text gets in, score each risk as likelihood × impact on the board, and agree a control and an owner for the top three.

Practice questions · for you

Map your school's AI risks

AI security · Level 4 · Lesson 1

1 **The marking helper scores 6, and everyone agrees "somebody" should check it. Who owns the risk?**

- ◯ The company that made the tool
- ◯ Everyone on the staff, together
- ◯ One named person, with a date to check it

2 **Match each AI tool to the untrusted text it reads most.**

A homework helper that browses the web	• • • •	Pupils' essays
A marking helper	• • • •	Results from the tools it calls
The parents' WhatsApp bot	• • • •	Web pages
A room-booking agent	• • • •	Parents' messages

3 **The school's risk register lists each tool with its likelihood and impact (1–3). Print each tool's score (likelihood × impact) and its name, highest first, one per line, like 9 Parents' chatbot.**

```
risks = [("Marking helper", 2, 3),
         ("Parents' chatbot", 3, 3),
         ("Lesson planner", 2, 1),
         ("Timetable agent", 1, 3)]
scored = []
for name, like, impact in risks:
    print(name)
```

Write your program:

4 **Complete the code that flags the risks needing an owner: a score of 6 or more.**

```
for name, like, impact in risks:
    score = like _____ impact
    if score _____ 6:
        print(name, "needs an owner")
```

Word bank: >= < * +

5 **Which of these are untrusted input for a school's AI tools? Choose all that apply.**

- ☐ The instructions the school wrote and tested
- ☐ A result returned by a tool the agent called
- ☐ A web page the homework helper reads
- ☐ A parent's message to the school bot
- ☐ A pupil's essay given to the marking helper

✎ **Which AI tool at your school worries you most? Score it (likelihood × impact), and say who owns it today.**

Check your answers

Map your school's AI risks

AI security · Level 4 · Lesson 1

1 **One named person, with a date to check it**

A risk without a named owner and a review date is left to "somebody", and somebody rarely comes.

2 **A homework helper that browses the web — Web pages**
A marking helper — Pupils' essays
The parents' WhatsApp bot — Parents' messages
A room-booking agent — Results from the tools it calls

Each tool has its own path for text nobody at school wrote.

3

```
risks = [("Marking helper", 2, 3),
         ("Parents' chatbot", 3, 3),
         ("Lesson planner", 2, 1),
         ("Timetable agent", 1, 3)]
scored = []
for name, like, impact in risks:
    scored.append((like * impact, name))
scored.sort(reverse=True)
for score, name in scored:
    print(score, name)
```

Putting the score first in each pair lets sort() rank the risks; reverse=True puts the highest on top, where your attention should go first.

4

```
for name, like, impact in risks:
    score = like * impact
    if score >= 6:
        print(name, "needs an owner")
```

Risk is likelihood × impact, so the operator is *.

5 **A web page the homework helper reads; A pupil's essay given to the marking helper; A parent's message to the school bot; A result returned by a tool the agent called**

Anything the AI reads that the school didn't write can carry a hidden order or a mistake: web pages, essays, messages and tool results.
